## Experimental Section

**Reagents and Solvents.** THF and pentane were vacuum-transferred from degassed blue or purple stills containing sodium benzophenone ketyl. The pentane still contained 1% tetraglyme to dissolve the ketyl. Air- and moisture-sensitive materials were manipulated using vacuum line and syringe techniques. Weinreb amide **1** was prepared from cyclohexanecarboxaldehyde and N-methyl-N-methoxyhydroxylamine hydrochloride using literature procedures. [<sup>6</sup>Li]PhCCLi and [<sup>6</sup>Li, <sup>13</sup>C]PhCCLi were prepared and recrystallized in pentane using recrystallized [<sup>6</sup>Li]LiHMDS and commercially available phenylacetylene and [<sup>13</sup>C-1]phenylacetylene. The phenylacetylenes were vacuum-transferred from 4 Å molecular sieves.

**NMR Spectroscopic Analyses.** All tubes were prepared under helium and stored in a liquid nitrogen bath prior to analysis. Tubes were prepared using stock solutions and sealed under partial vacuum. Standard <sup>6</sup>Li and <sup>13</sup>C NMR spectra were recorded on a 500 MHz

spectrometer at 73.7 and 125.0 Hz respectively. The  $^6\text{Li}$  and resonances were referenced to 0.3 M [ $^6\text{Li}$ ]LiCl/MeOH at  $-90\text{ }^\circ\text{C}$  (0.0 ppm). The spectra were recorded with a three-channel probe designed to accommodate lithium and carbon pulses. The tube was transferred from the liquid nitrogen bath to a  $-78\text{ }^\circ\text{C}$  bath to thaw the solution, then quickly transferred into the spectrometer and shimmed off the proton spectrum.

**Rate Studies by In Situ ReactIR Spectroscopy.** IR spectra were recorded using an in situ IR spectrometer fitted with a 30-bounce silicon-tipped probe. The IR probe was inserted through a nylon adapter and FETFE O-ring seal into a cylindrical flask fitted with a magnetic stir bar and T-joint. The T-joint was fitted with a nitrogen line and septum for injections. The flask was heated under full-vacuum and flushed twice with nitrogen. PhCCLi was weighted in glove box and dissolved in THF before syringe-transferred to the IR vessel. Pentane was added to the vessel to make the total volume 10 mL. The solution mixture was cooled to  $-50\text{ }^\circ\text{C}$  in a thermostatted bath for 25 minutes. A background spectrum was recorded, followed by addition of 0.05 mL of a 1.0 M stock solution of **1** while stirring. Spectra were recorded every 30 seconds for 5 half-lives. The rates of acylation of lithium penylacetylide with Weinreb amide **1** were monitored by following the loss of **1** ( $1673\text{ cm}^{-1}$ ).

The disappearance of the amide **1** was fit to the equation  $[A]/[A_0] = a \cdot e^{-k_{\text{obsd}}t} + c$ .

Where  $[A]$  is the concentration of **1** at time “t” and  $[A_0]$  is the concentration of **1** at  $t = 0$ .

Term “c” is a measure of the amount of amide remaining at  $t = \infty$ , which is typically a positive number at  $\leq 5\%$  of  $[A_0]$ .
